SYSTEM AND METHOD FOR SAFEGUARDING DATA BETWEEN A DEVICE DRIVER AND A DEVICE

BACKGROUND OF THE INVENTION

5 Field of the Invention

The present invention relates to data encryption. More specifically, the present invention relates to safeguarding the transfer of data within a device.

Background Information

With the proliferation of computers and networks, the amount and availability
10 of digitized data available for viewing and listening has grown. However, with this growth in the amount and availability of information, content providers have desired greater protection of the data from unauthorized use.

In order to protect data from unauthorized use, conventional data protection techniques, such as, for example, data encryption, have been used to protect data
15 as it is being transferred over a network or between devices. Content providers use a number of well known encryption techniques to encrypt sensitive data before transmission from one device, such as, for example, a satellite receiving dish, to a second device, such as, for example, a computer or set-top box.

Different conventional types of encryption techniques are used depending
20 upon the source device of the data and the type of data bus being used for the transmission from one device to another. For example, data transmitted from a Digital Video Disk (DVD) player to a computer uses Content Scrambling System (CSS) encryption, and data transmitted over an IEEE 1394 bus use Digital Transmission Content Protection (DTCP). Data transmitted over other bus systems

use a number of other encryption techniques. In order to decrypt the data as it is received, devices need to be able to decrypt data using the variety of techniques that are used to encrypt the data. Thus, a device that receives both CSS and DTCP encrypted data needs to know the techniques for decrypting both types of encrypted
5 data.

The various encryption techniques employed only protect the data during transmission. Once the data is received, it must be decrypted in order for the receiving device to be able to process the data. Once the data is decrypted within the receiving device, the data is susceptible to unauthorized access and
10 manipulation.

Moreover, these conventional systems do not protect the data inside an open architecture device, such as a personal computer. Conventional systems do not control what applications access the incoming data-stream, nor allow those applications to access the incoming data stream without being aware of the data
15 originator outside the device.

SUMMARY OF THE INVENTION

According to one aspect of the invention, a machine readable medium provides instructions which when executed by at least one processor, cause the
20 processor to perform operations. The operations include encrypting a payload of a data-stream data block with at least one key before transmitting the data-stream from a first system to a second system, replacing a portion of the payload with a tag that identifies at least one decrypting key to the first system before transmitting the

data-stream from the first system to the second system, and setting a flag in a header of the data block that indicates that the payload has the tag before transmitting the data-stream from the first system to the second system.

5 BRIEF DESCRIPTION OF THE DRAWINGS

The present invention will be described by way of exemplary embodiments, but not limitations, illustrated in the accompanying drawings. Identical numerals indicate the same elements throughout the figures.

Figure 1 is one embodiment for a data safeguarding system block diagram;

DETAILED DESCRIPTION

In the following description, various aspects and details of the present invention will be described. However, it will be apparent to those skilled in the art
5 that the present invention may be practiced with only some or all aspects of the present invention. For purposes of explanation, specific numbers, materials and configurations are set forth in order to provide a thorough understanding of the present invention. However, it will also be apparent to one skilled in the art that the present invention may be practiced without the specific aspects and details. In other
10 instances, well known features are omitted or simplified in order not to obscure the present invention.

Some portions of the descriptions that follow are presented in terms of algorithms and symbolic representations of operations on data bits within a computer memory. These algorithmic descriptions and representations are the
15 means used by those skilled in the data processing arts to most effectively convey the substance of their work to others skilled in the art. An algorithm is here, and generally, conceived to be a self-consistent sequence of steps leading to a desired result. The steps are those requiring physical manipulations of physical quantities. Usually, though not necessarily, these quantities take the form of electrical or
20 magnetic signals capable of being stored, transferred, combined, compared, and otherwise manipulated. It has proven convenient at times, principally for reasons of common usage, to refer to these signals as bits, values, elements, symbols, characters, terms, numbers, or the like.

It should be borne in mind, however, that all of these and similar terms are to be associated with the appropriate physical quantities and are merely convenient labels applied to these quantities. Unless specifically stated otherwise as apparent from the following discussion, it is appreciated that throughout the description,

- 5 discussions utilizing terms such as "processing" or "computing" or "calculating" or "determining" or "displaying" or the like, refer to the action and processes of a circuit that can include a programmed computer system, or similar electronic computing device. A computer system manipulates and transforms data represented as physical (electronic) quantities within the computer system's registers and memories
- 10 into other data similarly represented as physical quantities within the computer system memories or registers or other such information storage, transmission or display devices.

The present invention also relates to apparatus including circuits for performing the operations herein. This apparatus may be specially constructed for 15 the required purposes, or it may include a general purpose computer selectively activated or reconfigured by a computer program stored in the computer. Such a computer program may be stored in a computer readable storage medium. A machine readable medium includes any mechanism that provides (i.e. stores and/or transmits) information in a form readable by a machine such as a computer. For 20 example, a machine readable medium includes, and is not limited to, read only memory (ROM); random access memory (RAM); magnetic disk storage media; optical storage media; flash memory devices; electrical, optical, acoustical or other

form of propagated signals (such as carrier waves, infrared signals, digital signals, and so forth),, or any type of media suitable for storing electronic instructions.

The algorithms and displays presented herein are not inherently related to any particular computer or other apparatus. Various general purpose systems may
5 be used with programs in accordance with the teachings herein, or it may prove convenient to construct more specialized apparatus to perform the required method steps. The required structure for a variety of these systems will appear from the description below. In addition, the present invention is not described with reference to any particular programming language. It will be appreciated that a variety of
10 programming languages may be used to implement the teachings of the invention as described herein.

Various operations will be described as multiple discrete steps performed in turn in a manner that is most helpful in understanding the present invention, however, the order of description should not be construed as to imply that these
15 operations are necessarily order dependent, in particular, the order the steps are presented. Furthermore, the phrase "in one embodiment" will be used repeatedly, however the phrase does not necessarily refer to the same embodiment, although it may.

Figure 1 is a block diagram of one embodiment for a data safeguarding system 100. Data safeguarding system 100 includes data safeguarding device 104, protocol specific input devices 110 and protocol specific buses 120. Data safeguarding device 104 includes decoding devices 102, and a protected content exchange (PCX) module whose preferred embodiment includes a memory 108, and

a CPU **115** that executes programmed instructions stored in a memory **108**. PCX module **106** includes a number of protocol specific exchange modules **130**.

Protocol specific encrypted data is received over protocol specific bus **120** from protocol specific input devices **110**. In the Figure 1 example, encrypted data 5 may be received over a 1394 DTCP bus from a number of input devices **110** such as a satellite dish or video recorder (VCR). Any of a number of protocol specific buses **120** may be connected to data safeguarding device **104** including, for example, a USB bus, a PCI bus, and a DVD bus. Once the encrypted data is received by data safeguarding device **104**, CPU **115** directs the input to PCX 10 module **106**. Within PCX module **106**, the appropriate protocol specific exchange module **130** is used to decrypt the encrypted input data stream. For example, if IEEE 1394 DTCP bus encrypted data is received, a DTCP exchange module **130** would be used to decrypt the input data. Input data is received and is decrypted on a block-by-block basis.

15 Initially, PCX module **106** negotiates a content channel encryption key with protocol specific input device **110**. PCX module **106** then negotiates a PCX session key with the client decoding device **102**. Decoding device **102** is the client that, in one embodiment, originally requested the data from device **110**. Once the PCX session key is negotiated, PCX module **106** re-encrypts the payload of the protocol 20 specific data using a randomly generated PCX content key and transfers the re-encrypted data (including header and payload) to the appropriate decoding device **102**. Once decoding device **102** receives the re-encrypted data, decoding device

102 negotiates with the PCX module 106 to retrieve the PCX content key encrypted by the PCX session key. Once the appropriate PCX content is retrieved, decoding device 102 decrypts the payload data. Decoding device 102 then manipulates the unencrypted data. In one embodiment, decoding device 102 decodes the

- 5 unencrypted data. For example, if MPEG data is requested by an MPEG decoder, the appropriate input device 110 sends the data over the bus 120 to data safeguarding device 104. CPU 115 executes the PCX module 106 which decrypts the MPEG input data stream using a content channel encryption key for the bus 120. The MPEG decoder and PCX module 106 negotiate a PCX session key. The
- 10 payload MPEG data is re-encrypted with the randomly generated PCX content key and the re-encrypted data is sent to the MPEG decoder. PCX module 106 encrypts the PCX content key with the PCX session key. The MPEG decoder retrieves the encrypted PCX content key and decrypts the PCX content key with the PCX session key. In addition, the MPEG decoder uses the PCX content key to decrypt the
- 15 payload data for playback. The MPEG decoder then retrieves the device key and decrypts the payload data for playback.

In one embodiment, data within system 100 is further protected from tampering or from unauthorized access by the use of a number of anti-tampering techniques such as, for example, self-modification of PCX module 106 code, the

- 20 use of anti-debugging techniques, self-verification of PCX module 106 code, signature verification of PCX module 106 code, and other applicable anti-tampering techniques. The use of these anti-tampering techniques prevents unauthorized

access or modification of PCX module **106** code which prevents the unauthorized access or modification of the data as it is being transferred through system **100**.

Figure **2** is a block diagram of one embodiment for an architecture of a data safeguarding system **100**. Referring to Figure **2**, encrypted protocol specific data is received over IEEE 1394 bus **220** and transferred to IEEE 1394 bus driver **210**. Bus driver **210** then sends the protocol specific data to class driver **212**. PCX module **106** intercepts the protocol specific data and decrypts the data with a content channel encryption key. The content channel encryption key has originally been negotiated between PCX module **106** and protocol specific input device **110** before transmission. Once the data is decrypted, PCX module **106** re-encrypts only the MPEG portion of the payload of the data with a randomly generated PCX content key and encrypts the PCX content key with the appropriate PCX session key. This is repeated for the AC3 portion of the payload with a different randomly generated key and a different PCX session key. PCX module **106** sends the re-encrypted data back to class driver **212**. The re-encrypted data is transferred to a splitter **232** which splits the data between the various decoding devices. In the figure **2** example, the splitter **232** splits the IEEE 1394 re-encrypted data to AC3 device **216** and MPEG device **218**. MPEG decoder **218** and AC3 decoder **216** receive the appropriate encrypted PCX content key. MPEG decoder **218** and AC3 decoder **216** decrypt their PCX content key with their PCX session key. MPEG device **218** and AC3 device **216** then decrypt the re-encrypted data for playback using the appropriate PCX content key.

Thus, the data is protected from unwarranted hacking or copying within data safeguarding system 100. Within data safeguarding system 100, the transmission headers of the data are left decrypted while the payload of the data is re-encrypted by PCX module 106. Thus, the payload of the data is protected from unwarranted

5 copying or hacking during transfer within system 100 while allowing untrusted components to access the portions of the data stream they need.

Figure 3 is a block diagram of another embodiment of an architecture of a data safeguarding system 100. Referring to Figure 3, protocol specific input device 110 initially negotiates a content channel encryption key with protocol specific

10 registration engine 326. Protocol specific input device 110 transmits the encrypted protocol specific data via protocol specific bus 120 to bus driver 312. Bus driver 312 transfers the encrypted protocol specific data to device specific mini port driver 316 via protocol specific class driver 314. Protocol specific bus abstractor 320 abstracts the encrypted protocol specific data from device specific mini port driver 316. The

15 extracted encrypted data is transferred to PCX module 106. Within PCX module 106, the encrypted protocol specific data is decrypted using protocol specific decryptor 322. Protocol specific decryptor 322 decrypts the protocol specific data one block at a time. Each block of data contains a transmission header portion and a payload. In one embodiment, both the transmission header and payload portions

20 are encrypted during transmission from source device 110 to data safeguarding system 100. In an alternate embodiment, only the payload may be encrypted.

Depending on the specific data bus transmission protocol being used, protocol specific decryptor **322** decrypts either the entire data block or the payload only.

Each data bus transmission protocol requires a corresponding protocol specific decryptor **322**. PCX negotiator **328** negotiates a PCX session key with the
5 decoding device **102** that is the intended recipient of the protocol specific data.

Once a session key is negotiated, protected content exchange (PCX) encryptor **324** re-encrypts the payload portion of the data with a randomly generated PCX content key to produce re-encrypted data. PCX encryptor **324** transfers the re-encrypted data to protocol specific bus abstractor **320** which, in turn, transfers the re-encrypted
10 data to device specific mini port driver **316**. Device specific mini port driver **316** sends the PCX re-encrypted data to the upstream drivers and libraries **330** which in turn transfers the PCX re-encrypted data to splitter **232**.

Splitter **232** reads the transmission header of each re-encrypted data block and transfers the data block to the decoding device **102** corresponding to the
15 information contained within the transmission header. In addition, in one embodiment, splitter **232** removes the transmission headers from the data block. Within the data, data blocks are intermingled so that a variety of data blocks are received by splitter **232**. Thus, a video block may be received, then an audio block, then another video block, and so forth. The splitter transfers the payload sections of
20 the blocks to the corresponding decoding device as indicated by the transmission header. Once the re-encrypted payload data is received by a decoding device **102**, decoding device **102** retrieves the encrypted PCX content key from PCX negotiator

328. Decoding device **102** decrypts the content key using its PCX session key which was originally negotiated with PCX negotiator **328**. The unencrypted data is then consumed by decoding device **102**.

Figure 4 illustrates an exemplary architecture of safeguarding system 100.

- 5 Referring to figure 4, protocol specific input device **110**, such as a VCR, negotiates with a playback device such as MPEG decoder **435** to transmit a stream of encrypted data to MPEG decoder **435**. Protocol specific input device **110** initiates the transmission of a stream of encrypted protocol specific data marked with the appropriate copy protection status (i.e., "copy-1-generation," "copy-never," or "no-more-copies"). The copy protection status is transmitted via the encryption mode indicator (EMI) bits within the transmission header of the data. If data requested by
- 10 decoding device **102** (such as an MPEG decoder **435**) is copy protected, protocol specific input device **110** may choose to transmit an empty data stream until at least one decoding device **102** has completed the appropriate authentication procedure
- 15 required to access the content stream. Within data safeguarding system 100, protocol specific input device **110** negotiates authentication through PCX negotiator **328** and not directly with protocol specific input device **110**. In the figure 4 example, VCR **110** negotiates authentication with DTCP registration engine **426**. Once
- 20 protocol specific input device (VCR) **110** and DTCP registration engine **426** have completed the required AKE procedure, a content channel encryption key may be exchanged between protocol specific input device **110** and DTCP registration engine **426**. This content channel encryption key is used to encrypt the data by

protocol specific input device **110** and decrypt the IEEE 1394 encrypted data by DTCP decryptor **422**.

Once the content channel encryption key is negotiated, IEEE 1394 encrypted data is transferred from protocol specific input device **110** via IEEE 1394 bus driver

- 5 **210**, to class driver **212** and eventually to device specific mini port driver **416**. DTCP bus abstractor **420** abstracts the IEEE 1394 encrypted data from device specific mini port driver **416** and transfers the IEEE 1394 encrypted data to PCX module **106**. The IEEE 1394 encrypted data is decrypted by DTCP decryptor **422** one block at a time using the content channel encryption key previously negotiated by DTCP
- 10 registration engine **426**. In the IEEE 1394 example, both the transmission headers and the payload are encrypted by protocol specific input device **110**. Thus, DTCP decryptor **422** decrypts both the transmission header and payload portions of the IEEE 1394 encrypted data block.

If video decoder **438** has not previously registered with PCX module **106**,

- 15 PCX negotiator **428** authenticates video decoder **438**. During authentication, video decoder **438** is registered with PCX negotiator **428** and video decoder **438** negotiates a key exchange with PCX negotiator **428**. The key exchange method between video decoder **438** and PCX negotiator **428** is similar to the key exchange method between decoding device **110** and DTCP registration engine **426** described above. Once a session key is negotiated between video decoder **438** and PCX negotiator **428**, PCX encryptor **424** encrypts the payload of the data blocks using a randomly generated PCX content key. The re-encrypted IEEE 1394 data blocks are
- 20

transferred to DTCP bus abstracter **420** for transfer to device specific mini port driver **416**. The re-encrypted IEEE 1394 data is transferred via WDM stream class driver **430** and WDM streaming library **432** to source filter **434**. At source filter **434**, re-encrypted IEEE 1394 data intended for MPEG decoder **435** is split off from the
5 other IEEE 1394 data and transferred to MPEG decoder **435**. The re-encrypted IEEE 1394 data is muxed as MPEG transport stream (TS) to MPEG TS splitter **436**. MPEG TS splitter **436** splits the video and audio portions of the MPEG TS and removes the transmission headers. The video portion of the TS is transferred to video decoder **438**. Video decoder **438** requests the PCX content key from PCX
10 negotiator **428**. PCX negotiator **428** encrypts the PCX content key with the appropriate PCX session key and transfers it to video decoder **438**. Video decoder **438** decrypts the PCX content key using the previously negotiated PCX session key and used the content key to decrypt the video data. In addition, the video decoder **438** consumes the data. In a similar manner, audio decoder **440** receives the audio
15 TS and decodes the audio TS with a device key retrieved from PCX negotiator **428**.

In standard MPEG video, the audio and video blocks are interwoven together within the input data stream. In order to separate the data, the MPEG splitter **436** reads the transport stream headers. Within data safeguarding system **100**, MPEG decoder **435** only needs to use the PCX specific protocols in order to interact with
20 PCX negotiator **428** and does not need to be able to use each individual data bus transmission protocol. PCX module **106** is able to translate the encrypted protocol specific data from any specific bus into PCX encrypted data that the MPEG decoder

435 is able to understand and decode. Thus, the re-encryption of the protocol specific data by PCX module 106 is independent of any specific bus protocol used by system 100. Decoding devices 102 are independent of the command protocol of the specific bus. The bus abstractor 420 abstracts the DTCP status structure,

- 5 encapsulates the status structure in the proper command protocol, and transmits the encapsulated protocols to the driver 416 and vice versa. In this manner, decoding devices 102 are capable of receiving encrypted data from any protocol specific bus 120 without negotiating the content channel encryption key with the input devices 110 or knowing the encryption protocol for the specific buses 120. As existing bus
- 10 protocols change and new bus protocols are developed, PCX module 106 may be updated. However, decoding devices 102 only need to be able to talk with PCX module 106 and only need to be updated when the PCX module 106 negotiation protocols are updated.

PCX module 106 may be implemented in software or hardware. The PCX module 106 may be incorporated within RAM memory of a personal computer or may be contained within flash memory which is attached to a CPU or other data processing device. Thus, PCX module 106 is easily updated independent of decoding devices 102.

- 20 Figure 5 is a block diagram of one embodiment for a protected content exchange (PCX module 106). Referring to Figure 5, PCX module 106 contains protocol specific decryption modules 500, PCX encryption modules 510, protocol specific registration modules 520, and PCX negotiation modules 530. A protocol

specific decryption module **500** may be maintained for each protocol specific bus connected to data safeguarding system **100**. Thus, PCX module **106** may contain decryption module **1 (502)** through decryption module **n (504)**. PCX module **106** may contain a number of PCX encryption modules **510**. Thus, PCX module **106**

- 5 may contain PCX encryption module **1 (512)** through PCX encryption module **n (514)** for the encryption of a number of devices. In an alternate embodiment, only one PCX encryption module **510** may be maintained.

PCX module **106** includes a number of registration modules **520** for the negotiation of content channel encryption keys with protocol specific input devices

- 10 **110**. In one embodiment, PCX module **106** may contain registration module **1 (522)** through registration module **n (524)** corresponding to each protocol specific bus connected to the system.

PCX module **106** contains PCX negotiation modules **530** which are utilized by data safeguarding system **100** to negotiate key exchanges with decoding devices

- 15 **102**. In addition, the negotiation modules authenticate the decoding devices and maintain key synchronization between PCX module **106** and decoding devices **102**.

In one embodiment, PCX module **106** includes from negotiation module **1 (532)** through negotiation module **n (534)** corresponding to individual decoding device **102**.

- 20 Figure **6A** is a block diagram of one embodiment of an encrypted data stream **600**. Referring to Figure **6A**, encrypted data stream **600** contains a number of blocks of data, each block containing a transport header **602** and a payload **604**. In

one embodiment, the payload **604** and the transport stream header **602** may be 188 bytes in length. Within the encrypted data stream **600**, each block of data may be for a different device **102**. For example, MPEG audio and video data may be interleaved within encrypted data streams **600**. In addition, MPEG audio and video
5 data may be interleaved with AC3 and other data.

Referring now to figure **6B**, in an embodiment of the present invention a PCX data block **606** sent from a PCX module **106** to an application decoder **102** includes both a header **608** portion and a payload **616** portion. The header **608** portion is generally conventional and includes conventional block characteristic information,
10 and a flag **609** of the present invention that indicates whether the payload **616** of the block data contains a tag **610**, or alternatively whether the payload contains a PCX encrypted data. In one embodiment, the header **608** is a packetized elementary stream (PES) header. The payload **616** portion of the present invention includes the tag **610** at a predetermined position that includes an identifier information that can
15 be sent to the PCX module for accessing the decryption key(s) for the payload as well as preferably a portion of the payload replaced by the tag, disclosed presently. The tag preferably includes a stream identifier datum **612** for distinctly identifying the data stream, and a source datum **614** for distinctly identifying the stream source, enabling the application decoder **102** to transmit to a PCX module a message that
20 requests the decryption keys and preferably the portion of the payload for the identified data-stream from a PCX module that can access the decryption keys and preferably portion of the payload. In a safeguarding system **104** in which a data-

stream identifier unambiguously includes the data sufficient to access the decryption keys and preferably the portion of the payload, the tag should only include the data-stream identifier. In other systems, particularly those have a plural number of PCX modules, the tag should also include an additional datum such as the source datum

5 **614.** When the payload includes the tag **610**, the encrypted data stream is modified to replace a portion of the payload that is the size of the tag, with the tag. Thus, the payload content data **616** of the present invention is an encrypted form of the conventional data block that has a smaller portion replaced by the tag **610**. This shall be presented more in subsequent paragraphs with reference to figures **14** and
10 **17.**

Referring now to figure **14**, the block diagram depicted includes the PCX module **106**, and the decoders **102**, that contain circuitry of the present invention. The preferred embodiment of the application decoder **102** and the PCX module **106** each include a processing unit that responds to program instructions of the present
15 invention. Alternatively, as is well known to practitioners of the art, the circuitry does not require a processing unit and can be implemented as a fixed digital circuit without the configurable circuit advantages provided by a programmed processing unit.

The source device **110** transmits an exemplary two intertwined data-streams,
20 a video data-stream and an audio data-stream, to a device specific driver stack **1410** of data safeguarding device **104** via a bus **1420a**. Each data-stream includes a sequence of data blocks, each data block having a conventional header and

payload. The driver stack **1410** retransmits each data-stream to an appropriate PCX module **106**. The PCX module **106** includes at least one decryptor and protocol specific registration engine, and at least one PCX encryptor and PCX negotiator, described herein with reference to figures **3** and **4**. Each data-stream
5 transmitted from the source device **110** is optionally encrypted. The data-stream payloads are each encrypted by a PCX module **106** before transmission to an application decoder **102**, or alternatively optionally encrypted by a PCX module **106** if an individual data stream was transmitted from a source device **110** encrypted, and subsequently decrypted, by the PCX module **106**, so as to distinctly encrypt the
10 data within the data safeguarding device **104**.

The embodiment portrayed in figure 14 includes an application decoders 102a and 102b that are each a physically separate device from the PCX module 106. There are two separate data transmission channels connecting the PCX module 106 to each physically separate application decoder 102a and 102b. One of the separate data transmission channels transmits the data-stream from the PCX module 106 to the application decoder. The other separate data transmission channel transmits the non-data-stream data between the PCX module 106 and an application decoder 102, so these transmissions do not impact other components that access the data-stream transmission. In the embodiment portrayed in figure 14, each channel is a separate physical transmission line.

The data-stream data transmission path includes the PCX module 106 that sends the exemplary intertwined data-stream to a driver stack 1410. The driver

stack 1410 sends the data-stream to a splitter 1432, wherein each separate data-stream is then separated and separately transmitted to an appropriate exemplary application decoder 102a or 102b. The video data-stream is routed to the exemplary video application decoder 102a, and the exemplary audio data-stream is routed to

- 5 the exemplary audio application decoder 102b. The non-data-stream data transmission path between the PCX module 106 and the decoder 102a is exemplary bus 1460a, and between the PCX module 106 and the decoder 102b is exemplary bus 1460b, wherein buses 1460a and 1460b may be identical physical devices.

The non-data-stream data includes the identifier necessary for the PCX module to

- 10 access the data block decryptor keys and optional portion of the payload. The non-data-stream data preferably includes a data-stream identification datum and a source identification datum from the decoders 102a and 102b, and the encryption keys and the portion of a replaced payload from the PCX module 106. The preferred embodiment non-data-stream data additionally includes an authentication
- 15 and key exchange (AKE) from the PCX module 106 to the exemplary application decoders 102a and 102b to enable a separately encrypted tag and the aforementioned encryption keys to be themselves encrypted, assuring the embodiment of an authorized and secure decoder(s) 102 in communication with the PCX 106 module and receiving the data-stream. The precise method of transmitting
- 20 and receiving the data-streams, datum identifiers, and encryption keys, shall be described with reference to figure 17.

0006259276-0006260000

Referring now to figure 15, a programmed processor embodiment of the PCX module 106 runs on a computer system that can include an exemplary unitary processor 1510 that processes data signals. The processor 1510 may be a complex instruction set computer (CISC) microprocessor, a reduced instruction set 5 computing (RISC) microprocessor, a very long instruction word (VLIW) microprocessor, a processor implementing a combination of instruction sets, or other processor device. However, it is understood that the present invention may be implemented in a computer system having multiple processors. The processor 1510 is coupled to a CPU bus 1520, or other communication device for communicating 10 information, that transmits data signals between processor 1510 and other components in the PCX module 106. The computer system includes a memory 1530, or other computer readable media that is commonly a random access memory (RAM) device or other dynamic storage device, that can be used to store temporary variables or other intermediate information during execution of 15 instructions by processor 1510, and is coupled to the bus 1520. The PCX module 106 also includes a read only non-volatile memory such as a semiconductor Read Only Memory (ROM) device, and/or other static storage device 1540 coupled to bus 1520 for storing static information and instructions for processor 1510. Data storage device 1550 is another computer readable medium coupled to bus 1520 for storing 20 information and instructions, and can be such exemplary computer readable media as magnetic disk, and/or an optical disk and corresponding drives. Display 1560 is coupled to bus 1520 for displaying data generated by the processor 1510, and

mouse 1570, or other exemplary selecting or pointing device, and keyboard 1580, each couple to the bus 1520.

Referring to figure 16, a PCX module 106 includes a programmed processing device 1605 that accesses a memory unit 1615 for transmission of the encrypted 5 data stream to that memory unit 1615, and for transmission of the key(s) and tag data. The system includes the exemplary application decoders 1610, embodied by an exemplary video data application decoder 1610a and an exemplary audio data application decoder 1610b. The application decoders 1610 each access the memory unit 1615 for the encrypted data stream. The tag data is read by the 10 decoders 1610, and sent back to the memory unit 1615, for access by the PCX computing device 1605, and a placement of the relevant key(s) and portion of the payload into a memory location that a decoder 1610a or 1610b accesses for a read 15 of the key(s) and the replaced portion of payload data. Alternatively, the PCX computing device 1605 can store the key(s) and payload portion in the memory unit for a direct read by an application decoder 1610 according to the content of the transmitted tag data. In another embodiment, as disclosed herein, the application decoder(s) 1610 and the PCX computing device can be embodied by a unitary computing device that executes both program instructions for the application decoder(s), and the PCX module.

20 Referring to figure 17, a preferred embodiment block diagram depicted includes the PCX module 1706, the decoders 1702, and the driver stack 1710 that contain circuitry of the present invention. As formerly described with reference to

figure 14, the source device 110 transmits an exemplary two intertwined data-streams to a device specific driver stack 1710 of data safeguarding device 104 via a bus 1420a. The data safeguarding device 104 includes a shared memory 1715. The driver stack 1710 moves each block to memory 1715 where it is written into a buffer 1715a of the memory 1715, and sends to the PCX module 1706 a pointer to the buffer 1715a for each block. The PCX module 1706 accesses each block according to its memory pointer and distinctly encrypts the data within the safeguarding device 104 as described with reference to figure 14.

- The PCX module 1706 additionally replaces a portion of the payload with the tag, and marks a flag, as described with reference to figures 6b and 14, and as will be described with reference to figure 18. The memory 1715 includes a second buffer 1715b that both the exemplary decoders 1702a and 1702b and the PCX module 1706 write to and read from for transmission between them of non-data stream data described with reference to figure 14, and figure 18. The PCX module 1706 may also include a splitter circuit that places a pointer in the buffer 1715b identifying to the application decoders 1702 the data-streams directed to each separate exemplary application 1702a and 1702b, or alternatively transmit that data over a separate physical line directly to the application decoders 1702 in a configuration that includes a pre-existing physical bus as depicted with reference to figure 14.
- The splitter circuit may be physically separate form the PCX module 1706 including a separate processor that may receive pointers directly from the driver stack 1710, and may write into a separate buffer in the memory 1710. In the embodiment herein

portrayed. The interface between a decoder **1702a** and **1702b** and the buffer **1715a** is a first channel, and the interface between a decoder **1702a** and **1702b** and the buffer **1715b** is a second channel.

Referring now to figure **18**, the method and circuit herein described applies
5 to a system of a decoding application **102**, portrayed with reference to both figure
14, wherein an exemplary video decoder **102a** and audio decoder **102b**, and a
physically separate PCX module **106**, in which a data stream is sent to the PCX
module from a source device **110**; and analogously to figure **17** as an exemplary
video decoder **1702a** and audio decoder **17102b**, and a physically separate PCX
10 module **1706**; as well as a system implemented by a processing device that is both
a PCX module and an application decoder(s). As has been described with
reference to figure **14**, the preferred circuit includes a programmed processing
device, but alternatively can be implemented by digital circuitry that does not include
a programmed processing device, or can be implemented alternatively by a
15 programmed processing device in at least one application decoder and/or the PCX
module, or a processing device that is embodied partially, but not completely, by a
programmed processing device.

The data stream transmitted to the safeguarding system is alternatively
unencrypted, or encrypted and has been decrypted by the PCX module as
20 described herein. At block **1805**, the PCX module not necessarily but preferably
performs an AKE procedure with each decoder to create a shared session key with
each decoder. This session key will be used to encrypt the decryption keys before

they are sent back to the decoder. Additionally this AKE will assure that the applications are authorized to access the PCX module encryption system. At block 1810, the PCX module encrypts the data block payload. The payload is encrypted using at least one key. At block 1815, the PCX source module stores a tag-sized
5 portion of the encrypted payload for subsequent transmission to an application decoder. In the preferred embodiment, the entire payload is encrypted using the key(s). In the present invention, the stored portion can alternatively be encrypted separately with the key(s), or can be optionally left unencrypted. The payload in a following block shall be decrypted in accordance with the encryption characteristic of
10 the stored portion.

At block 1820, a tag is inserted into the payload in the place of the saved payload portion. The tag includes in the preferred embodiment both an identification of the data stream 612 and an identification of the data stream source 614, the source identified because a safeguarding system may include more than one source
15 circuit. The encryption keys and the saved portion of the payload are each referenced to the data-stream identifier. At block 1825, a flag in the header is marked to indicate that the block contains a payload tag. At block 1830, the data block is sent to the appropriate decoder 102 along the data-stream transmission channel described with reference to figure 14, or alternatively described with
20 reference to figure 17. At block 1835, the appropriate application decoder has received the data block from the splitter 1432 with reference to figure 14. At block 1840 the application decoder that has received the data block reads the header flag

0987654321 - 0987654321

position and at block **1845** determines whether the header flag is marked. If the header flag indicates that the payload does not contain a marked flag, control passes out of this flow. If the header flag indicates that the payload does contain a tag, control passes to block **1850** where the data stream identifier datum and the
5 source datum are read and an identifier of each is sent back to each PCX module or alternatively, only the data stream identifier is sent back to the source module circuit identified by the source datum. In the embodiment in which the application decoder module, and the PCX module are physically separate devices, the identifier(s) are sent back to the PCX module along the separate channel as herein described.

10 At block **1855** the appropriate PCX module reads the data stream identifier. The proper application keys and portion of the payload are determined by reference to the data stream identifier. The second set of encryption key(s) and the stored portion of the payload that was replaced by the tag are transmitted to the target application decoder in accordance with the data stream identifier. In the
15 embodiment in which the application decoder module and the PCX module are physically separate devices, the identifiers are sent back to the PCX module along the separate channel as herein described. At block **1860**, the appropriate application decoder receives the decryption keys key(s) and the payload portion transmitted from the PCX module at block **1855**, and decrypts the key(s) with the
20 session key, replaces the payload portion from the tag position, and then decrypts the payload using the decrypted key(s).

Figure 7 is a block diagram of one embodiment for a shared buffer **700**. Shared buffer **700** includes a device specific header **710** and PCX resync blocks

720. Device specific header **710** includes a header data portion **712** and PCX content key **714**. In one embodiment, PCX resync blocks **720** contain from PCX resync block 1 (**722**) through PCX resync block n (**726**). Header data **712** identifies the decoding device **102** corresponding to the shared buffer **700**. In one embodiment, each decoding device **102** corresponds to a unique shared buffer **700**.

5 In an alternate embodiment, all decoding device **102** use a single, shared buffer **700**. Shared buffer **700** may be any applicable data structure such as, for example, an array, linked list, or other applicable data structure. PCX content key **714** is encrypted with the previously negotiated PCX session key and is the key that will be

10 used to decrypt the payload.

Figure 8 is a block diagram of one embodiment for PCX resync block 720. Referring to figure 8, PCX resync block 720 includes key delta tag 810, random initialization vector 815, and portion of the encrypted payload data 820. PCX resync block 720 is utilized for key synchronization as described below.

15 Figure 9 is a flow diagram of one embodiment for safeguarding protocol specific data within a device. Initially at processing block 905, data safeguarding system 100 receives encrypted protocol specific data. The encrypted protocol specific data may be encrypted for any of a variety of data bus security protocols such as, but not limited to Digital Transmission Content Protection (DTCP), Content 20 Scramble Systems (CSS), and Content Protection for Recordable Media (CPRM). The protocol specific data is received in processing blocks one block at a time.

At processing block 910, the encrypted protocol specific data is translated into protected content exchange (PCX) re-encrypted data. The translation of the data includes decrypting the encrypted protocol specific data using a content channel encryption key to produce decrypted data. Once the data is decrypted, the payload of the decrypted data is re-encrypted using a PCX content key to produce PCX re-encrypted data. The content channel encryption key is negotiated by a protocol specific registration engine 326 with protocol specific input device 110 upon initiation of the transfer of protocol specific data from the protocol specific input device 110 to decoding device 102. Once protocol specific input device 110 and protocol specific registration engine 326 have completed the required AKE procedure, a content channel encryption key may be exchanged between protocol specific input device 110 and protocol specific registration engine 326. This content channel encryption key is used to encrypt the data by protocol specific input device 110 and decrypt the encrypted protocol specific data by protocol specific decryptor 322. The session key is negotiated between PCX negotiator 328 and decoding device 102.

After the data is re-encrypted, the re-encrypted data and the PCX content key encrypted by the PCX session key are transferred to the decoding device **102** at processing block **915**. In one embodiment, the re-encrypted data is split into a number of data streams which are transferred to appropriate decoding devices **102**. At processing block **920**, decoding device **102** decrypts the PCX content key

and uses it to decrypt the re-encrypted data. The unencrypted data is further decoded by decoding device **102**.

Figure 10 is a flow diagram of one embodiment for decrypting re-encrypted data by decoding device **102**. Referring to Figure 10, decoding device **102** receives 5 re-encrypted data at processing block **1005**. At processing block **1010**, decoding device **102** retrieves the encrypted PCX content key from PCX negotiator **328**. If decoding device **102** is not registered, PCX negotiator **328** registers the protocol device **102** and negotiates the PCX session key for the protocol device **102**. At processing block **1015**, decoding device **102** decrypts the re-encrypted data using 10 the PCX content key.

Figure 11 is a flow diagram of one embodiment for creating a PCX resync block **720**. Initially at processing block **1105**, PCX module **106** receives protocol specific encrypted data. Next, at processing block **1110**, PCX module **106** determines if a new resync point has been reached. If a new resync point has not 15 been reached, processing continues at processing block **1130**. If a new resync block has been reached, processing continues at block **1111**. At processing block **1111**, PCX module **106** determines if PCX content key needs to be generated. If no new PCX content key needs to be generated, processing continues at processing 20 block **1115**. However, if a new PCX content key needs to be generated, processing continues at processing block **1112**.

At processing block **1112**, the new PCX content key is generated. PCX module **106** uses the existence of natural synchronization points within the original data stream to determine when to create a new PCX content key.

At processing block **1115**, PCX module **106** generates PCX tag **610** that is a unique identification for the PCX resync block **720**. In one embodiment, PCX tag **610** may be an array index value. In alternate embodiments, PCX tag **610** may be any suitable index value to the PCX resync block **720**. At processing block **1120**, PCX module **106** copies PCX flag **609**, PCX tag **610**, TSID **612**, and PID **614** into the payload portion of the data stream and saves the original portion in location **820** in the resync block **720**.

At processing block **1125**, PCX module **106** updates PCX resync data **720**. If the PCX content key being used to encrypt the payload is different from the PCX content key used on the previous block for the same decoding device **102**, key delta tag **810** is incremented. Otherwise, key delta tag **810** is unchanged. In this manner, PCX content keys may be changed periodically during re-encryption of the data.

This increases the security of the data within system **100**. In one embodiment, PCX content key is changed on a fixed time interval or after a fixed number of PES headers **608** have been processed.

In order to increase the security of system **100**, the PCX content key is altered on each PES header **608** change by using a random initialization vector as a seed value to modify the key. This allows splitter **232** to drop a data block without losing the ability to decrypt the remaining data in the input stream. In one

embodiment, key delta tag **810** and random initialization vector **815** are not encrypted. PCX content key **714** is encrypted with the previously negotiated PCX session key.

At processing block **1130**, PCX module **106** encrypts the payload containing
5 the resync data using the PCX content key.

Figure **12** is a flow diagram of one embodiment for decrypting a PCX resync block **720**. Initially at processing block **1205**, decoding device **102** receives a block of PCX encrypted data. At processing block **1210**, decoding device **102** decrypts the payload and determines if the block of data is a resync block. If not, processing
10 continues at step **1219**. If the block of data is a resync block, processing continues at block **1211**.

At processing block **1211**, decoder **102** checks if key delta tag **810** changed. Delta tag **810** indicates if PCX content key has changed. If so, at processing block **1213**, decoding device **102** retrieves PCX content key **714** from shared buffer **700**.
15 At processing block **1215**, decoding device **102** extracts PCX tag **610** and performs a look-up of the resync block **720** within shared buffer **700**. Decoding device **102** restores the original payload.

Decoding device **102** then decrypts the PCX content key using the previously negotiated PCX session key. At processing block **1218**, decoder **102** reinitializes
20 the decryption cipher using the PCX content key and the random initialization vector **815**.

At processing block **1219**, decoder **102** decrypts the payload using the decryption cipher. At processing block **1220**, the decoding device **102** decodes the payload of the unencrypted data for further processing (for example, playback by MPEG decoder).

- 5 The protocol specific data may contain copy control information (CCI) which allows the content owners to assign varying levels of priority for what can and can't be done with the data. The data may be "copy free" which means there is no restriction to copying the data. The other end of the spectrum is "copy never" which means that as soon as the AKE is negotiated, a device must render the data
- 10 immediately. In this scheme, a device can not make any copies, can not save the data for later use, or anything similar. Thus, when a device receives the data, it is sent to the consumer, and then the data gets thrown away.

The other two schemes are "copy once" and "copy no more." If a device receives data that is marked as "copy once," the device may make a single copy of 15 the data if the user chooses to do so. This scheme allows recording for later viewing. When a device receives data that is marked "copy once," the device may save it, but then once it is saved, when it is retrieved after saving, the device must mark the data as "copy no more."

In one embodiment, during transfer of data within system **100**, if the data is 20 unencrypted, the CCI information is susceptible to interception and unauthorized change. Thus, if the data is marked "copy never" and the information is hacked, the data may be pirated within system **100**. The CCI information is contained within

transmission header **602**. The transmission header **602** is not encrypted during transfer though system **100** and is susceptible to change.

Within system **100**, the CCI information is built into the PCX content key. The CCI information retrieved from the data stream in transmission header **602** is used 5 as part of the seed to generate the key. Thus, by combining the PCX content key with the control information before re-encryption, system **100** guarantees that any modification of the CCI information in the transmission header **602** will result in incorrect decryption of the protected data. During decryption of the re-encrypted data by decoding device **102**, the CCI information is extracted from the transmission 10 header **602** and combined with the PCX content key to create the decryption key.

The above method may be used to protect any information embedded within the transmission header **602**. Thus, information such as, for example, copy quality which may indicate the quality of audio a user is allowed to copy, how many times a device is allowed to copy this content, and similar information may be protected from 15 change while the data is transferred within system **100**.

Figure 13 is a block diagram of one embodiment for an information synchronizing system **1500**. Content exchange device **1510** is configured to receive fixed-size data **1505**. Content exchange device **1510** is further configured to save a portion of the original payload of the fixed-size data **1505** in shared memory buffer 20 **1540** and configured to save synchronization information together with the original portion in shared memory buffer **1540**. In one embodiment, decryptor **1525** is configured to decrypt fixed-length data **1505** as it is received by content exchange

device **1510**. Negotiator **1515** is configured to embed a tag to the appropriate synch block in shared memory buffer **1540** within a payload area of the fixed-size data **1505** to produce replacement data **1530**. In one embodiment, encryptor **1520** is configured to encrypt the payload of replacement data **1530** and configured to
5 encrypt the original payload saved in shared memory buffer **1540**.

Decoding device **1535** is configured to extract the embedded tag from replacement data **1530** and to retrieve the original payload and synchronization information from shared memory buffer **1540** corresponding to replacement data **1530**.

10 In one embodiment, decoding device **1535** is contained within the same device as shared memory buffer **1540**. In an alternate embodiment, decoding device **1535** is a separate device from the device containing shared memory buffer **1540**.

While certain exemplary embodiments have been described and shown in
15 the accompanying drawings, it is to be understood that these embodiments are merely illustrative of and not restrictive of the broad invention. The present invention is not limited top the specific constructions and arrangements shown and described, and alternative embodiments will become apparent to those skilled in the art to which the present invention pertains without departing from the scope of the present
20 invention. The scope of the present invention is defined by the appended claims rather than the forgoing description. In the appended claims, a physical embodiment of each recited circuit limitation does not necessarily include completely separate

physical devices from another recited circuit limitation. An embodiment of each circuit may share at least one element with another circuit.
